- **3-jet event shape**
- **jet rate**
- **Summary**

# Deep Inelastic Scattering at HERA

Born process: QPM      QCD-Compton process      Bosphon-gluon fusion

- Study pQCD prediction and non-perturbative hadronization
- HERA-I data: 1995-2000,  $\mathcal{L} = 115 \text{ pb}^{-1}$ ,  $\sqrt{s} = 300/320 \text{ GeV}$
- Momentum transfer  $Q^2 \in (196, 40000) \text{ GeV}^2$  and inelasticity  $y \in (0.1, 0.7)$

# Breit frame in DIS

$$2x\vec{P} + \vec{k} = 0$$

Advantage of Breit frame

- proton remnant hemisphere (RH) with  $\eta > 0$
- Current hemisphere (CH) with  $\eta < 0$
- Current hemisphere: similar to  $1/2 e^+e^-$  collision

# 2-jet event shapes

---

- **first non-zero contribution at order  $\alpha_s$**
- **1 - Thrust:  $\tau \equiv 1 - T = 1 - \frac{\sum_h |p_{zh}|}{\sum_h |p_h|}$**
- **1 - Thrust related to the thrust axis:  $\tau_C \equiv 1 - T_C = 1 - \frac{\sum_h |p_h \cdot n_T|}{\sum_h |p_h|}$**
- **Jet broadening:  $B = \frac{\sum_h |p_{\perp h}|}{\sum_h |p_h|}$**
- **Jet Mass (massless in the p-scheme):  $\rho = \frac{(\sum_h p_h)^2}{(2 \sum_h |p_h|)^2}$**
- **C-parameter:  $\frac{3 \sum_{h,i} |p_h| |p_i| \sin^2 \theta_{hi}}{2(\sum_h |p_h|)^2}$**

**These are defined for the particles in the current hemisphere (CH) alone.**

# 2-jet event shapes

---

- Differential distribution of event shape  $F$

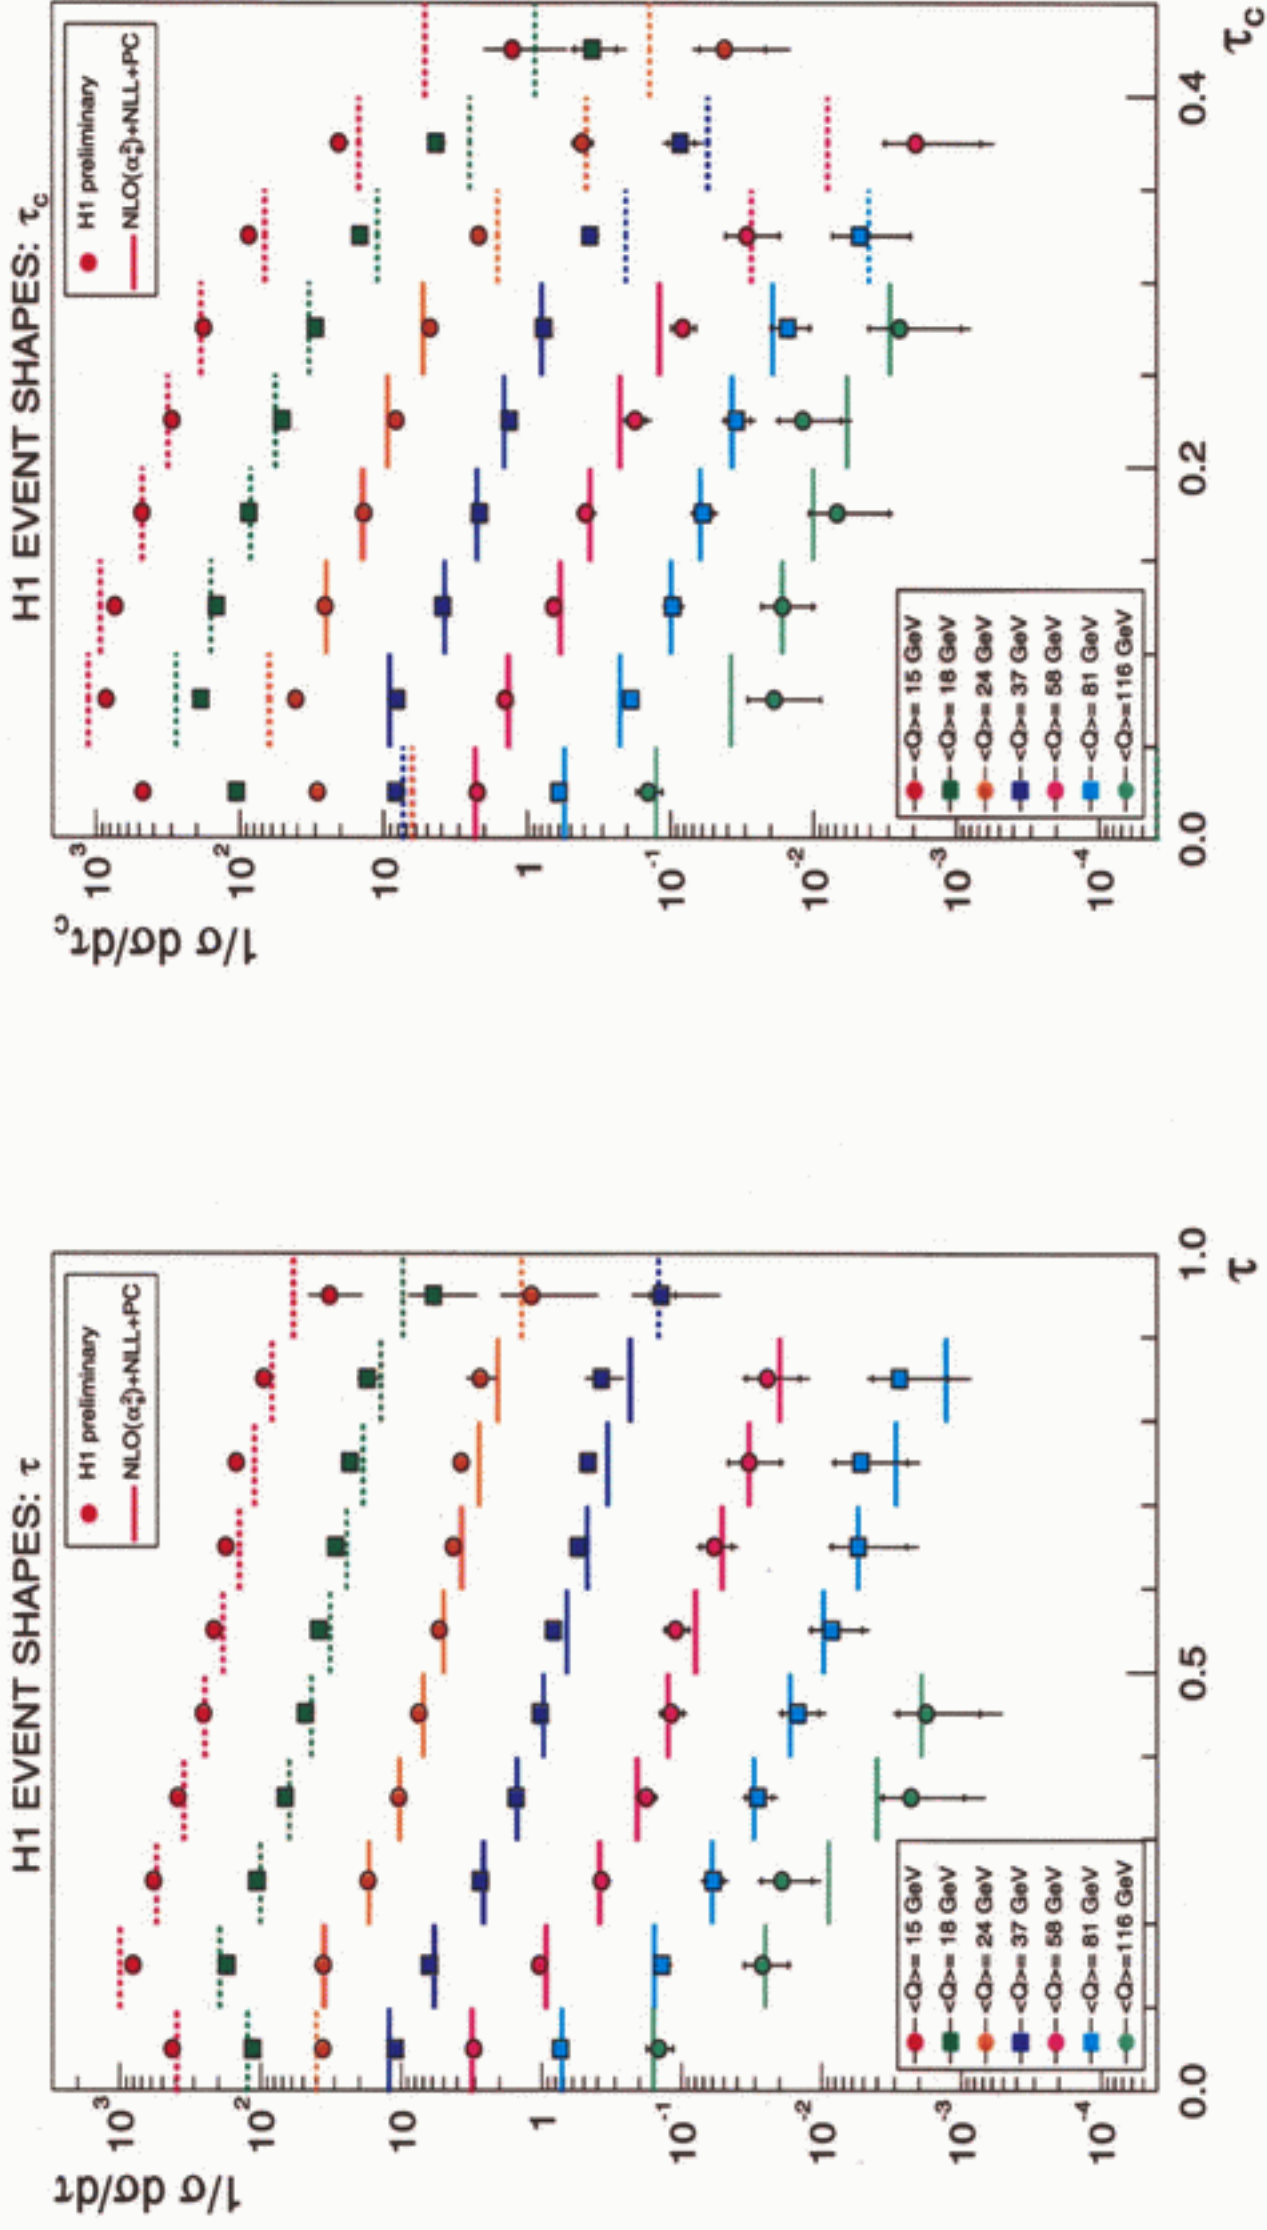

$$\frac{d\sigma(F)}{dF} = \frac{d\sigma^{pQCD}(F - a_F \mathcal{P})}{dF}$$

$d\sigma^{pQCD}$  and  $a_F$ : pQCD calculation

$\mathcal{P}$ : power correction, non-perturbative effects

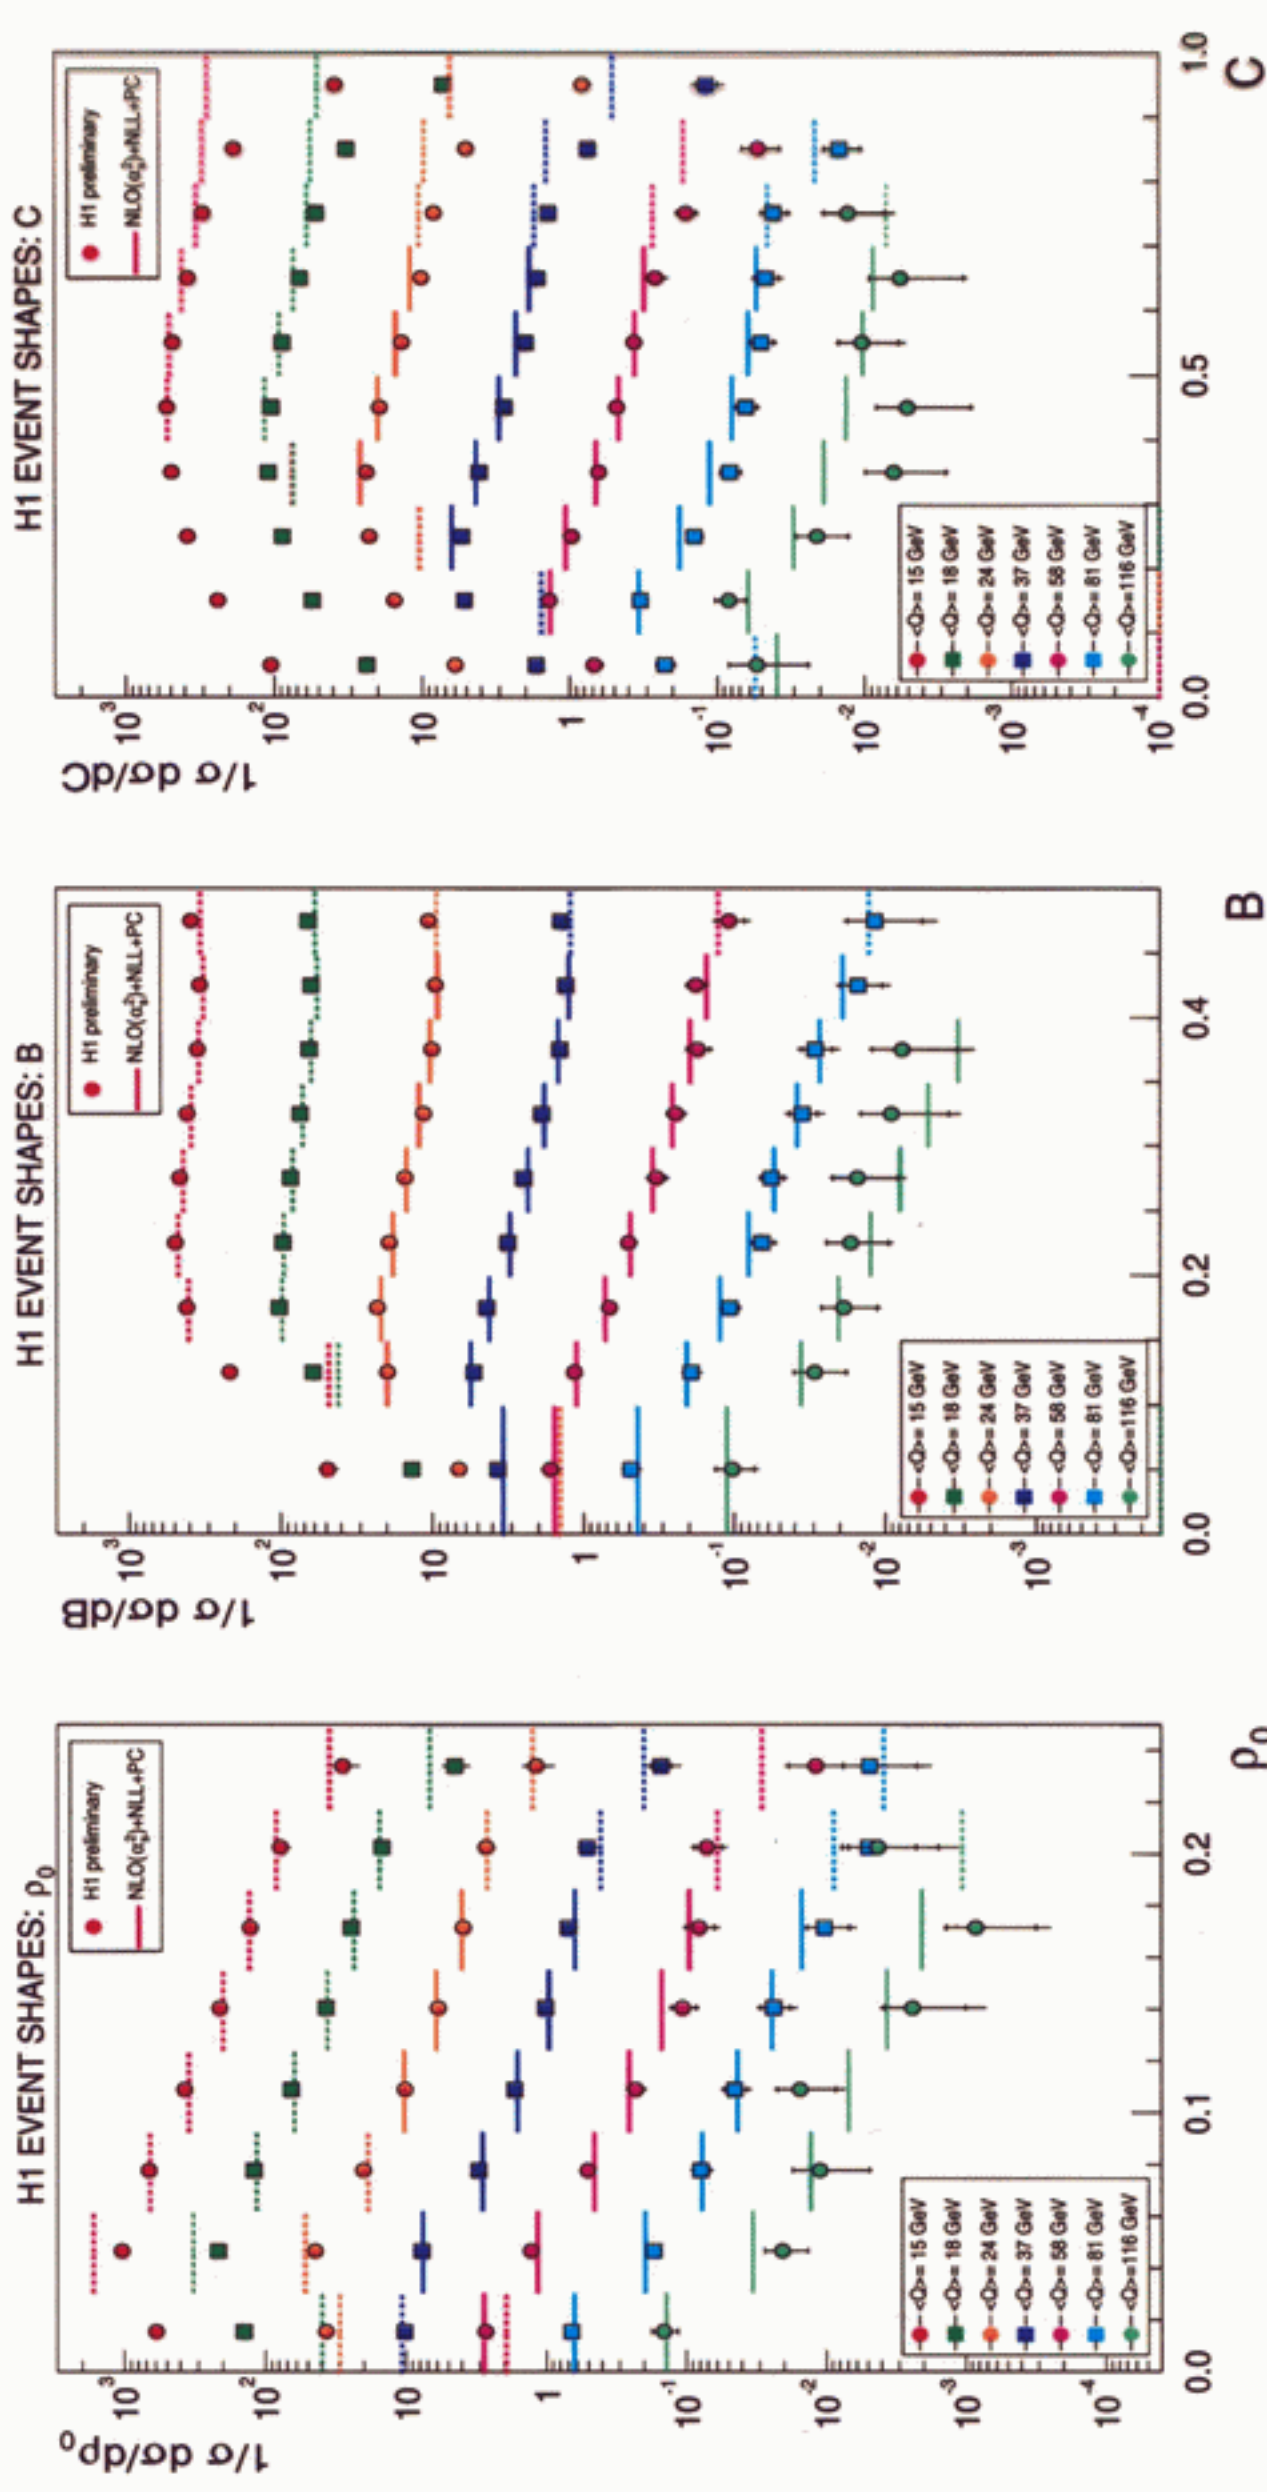

- $\mathcal{P}$ : universal for the observable and the process
- Power corrections have two free parameters  $\alpha_s$  and  $\bar{\alpha}_0(\mu_I = 2\text{GeV})$

# 2-jet event shapes

● data fitted well by pQCD and power correction

# 2-jet event shapes

● data fitted well by pQCD and power correction

# 2-jet event shapes

## Fitted results from distributions

- negative correlation between  $\bar{\alpha}_0$  and  $\alpha_s(M_{Z^0})$
- consistent with  $\bar{\alpha}_0 = 0.5$ , within 10%
- consistent value for  $\alpha_s(M_{Z^0})$  with world average

# 3-jet event shapes

---

- **first non-zero contribution at order  $\alpha_s^2$**
- $K_{out}$  : out-of-event-plane momentum for hadrons with  $\eta_{Breit} < 3.0$

$$K_{out}/Q \equiv 1/Q \sum' |p_h^{out}|$$

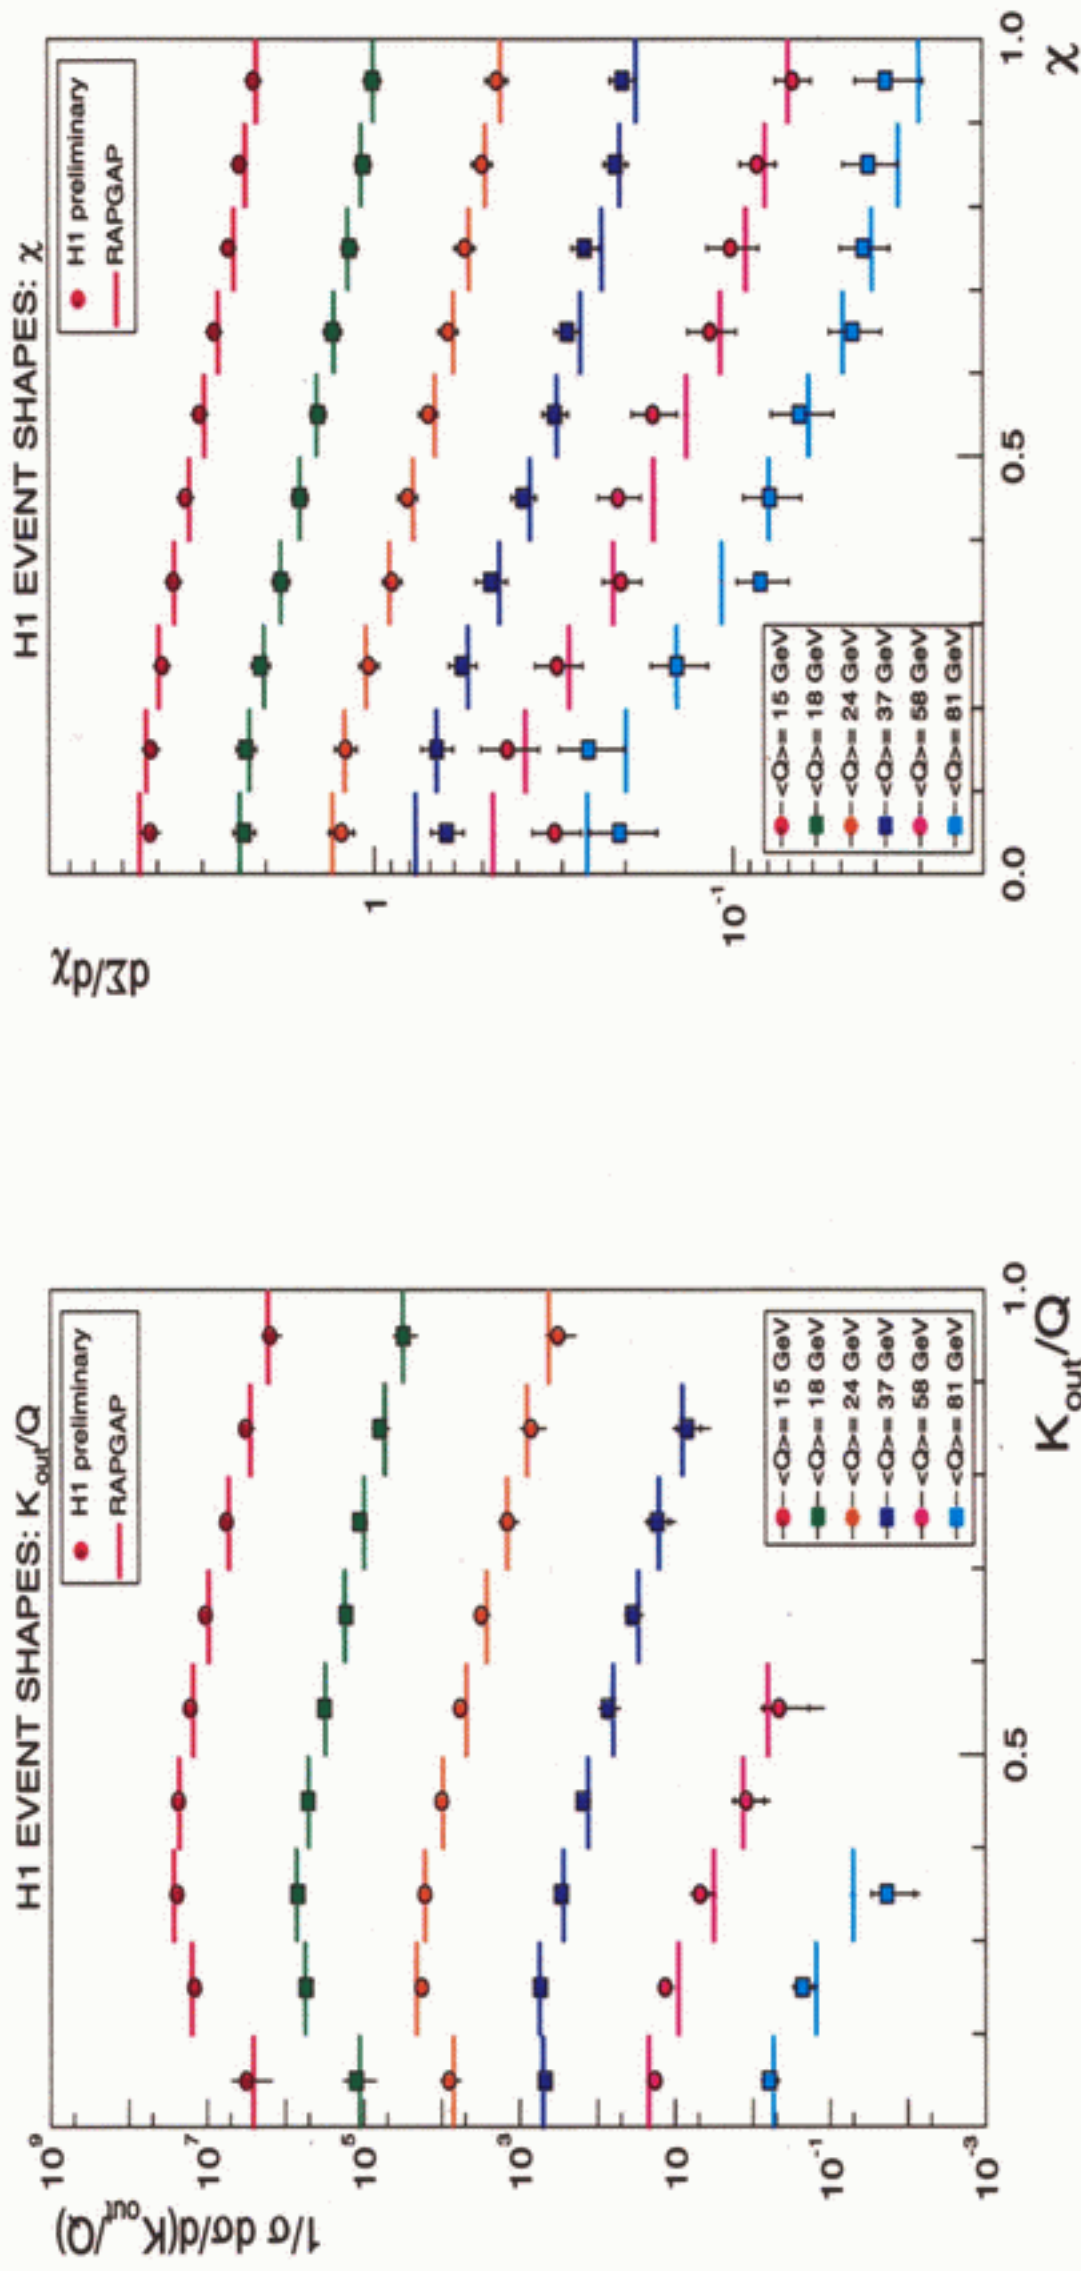

- $\chi$  : azimuthal correlation for hadrons with  $\eta_{Breit} < 3.0$

$$\chi \equiv \pi - |\phi_h - \phi_{h'}|, \text{ weighted by } w = p_{th} p_{th'} / Q^2$$

- LO, next-to-leading-log resummation and power correction available from A. Banfi et al. JHEP 11 (2001) 066 & JHEP 04 (2002) 024

# 3-jet event shapes

- RAPGAP Monte Carlo using LO matrix elements with parton showers
- $K_{out}$  and  $\chi$  are well described by RAPGAP

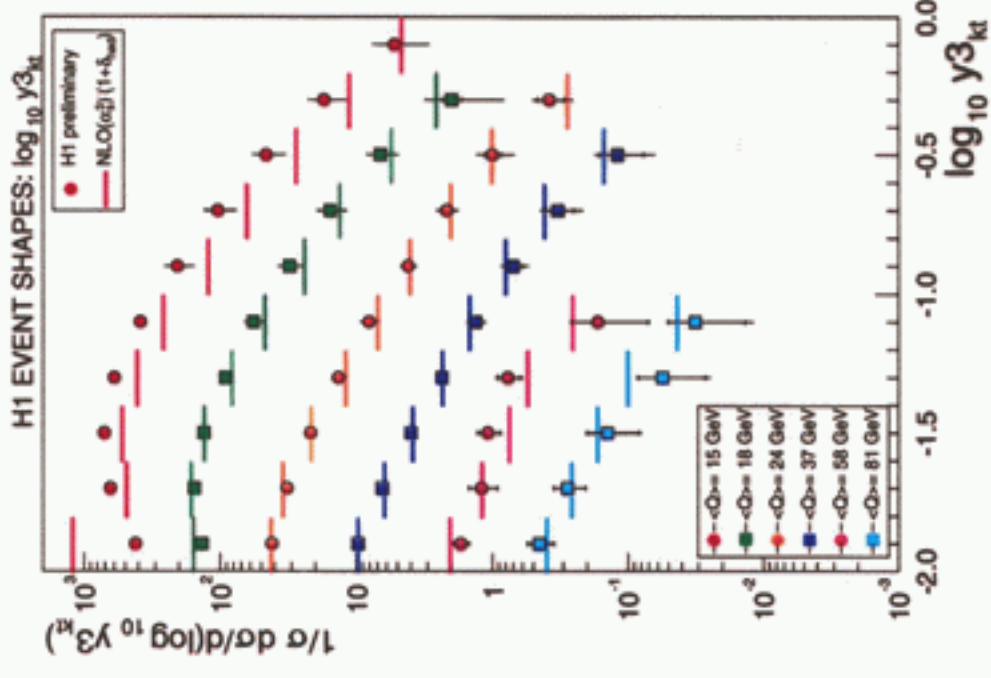

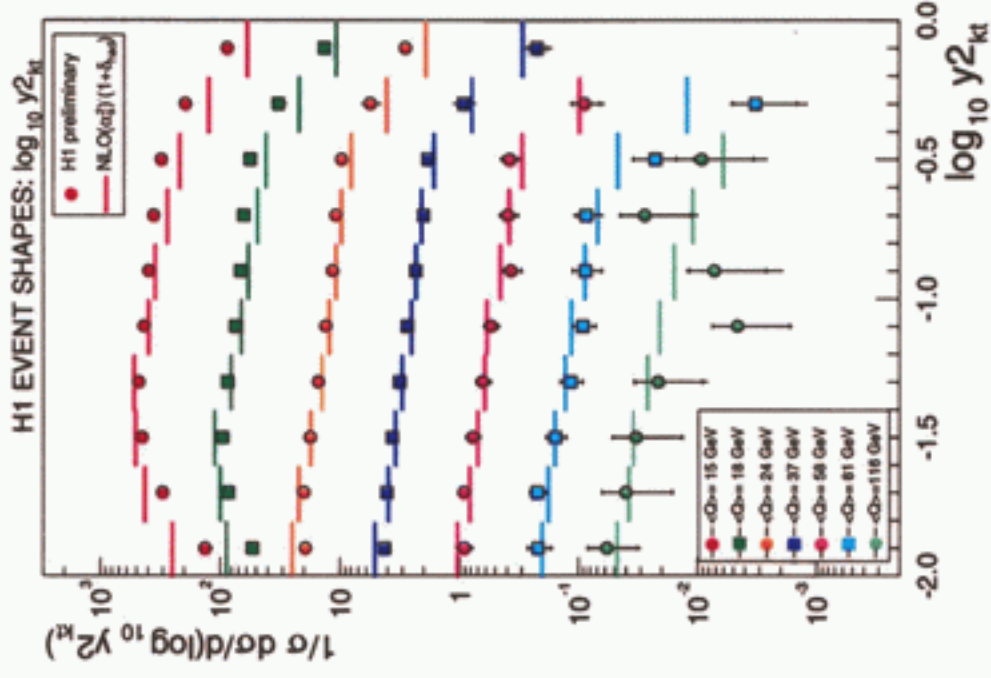

# Jet rate

- Jet finder: exclusive  $k_t$  clustering algorithm
- $y_2$ : the value of jet resolution parameter, where the transition  $1+1$  jets  $\rightarrow$   $2+1$  jets occurs.

- Jet rate  $y_n$ : the same for the transition  $(n-1)+1$  jets  $\rightarrow$   $n+1$  jets occurs.
- theory prediction:
  - Fixed order calculation in NLO for  $y_2$  and  $y_3$ , LO for  $y_4$
  - Resummation by A. Banfi et al.
  - Power corrections: not yet

# Jet rate

- NLOJET++ calculate (2+1)- and (3+1)-jet cross sections at NLO level and (4+1)-jet cross section at LO level.
- NLOJET++ give a good description of  $y_2$  and  $y_3$  for  $Q^2 \geq 576 \text{ GeV}^2$ .

# Summary

---

- Precision measurements of event shape have been performed.
- pQCD and power correction well describes 2-jet event shapes.
- A **first** measurement of 3-jet event shapes ( $K_{out}$  and  $\chi$ ) in DIS.  $K_{out}$  and  $\chi$  are described by Monte Carlo RAPGAP.
- NLOJET++ describes jet rate  $y_2$  and  $y_3$  for  $Q^2 \geq 576 \text{ GeV}^2$ .
